Spring 2020
Class Project Report
Project TITLE: Search engine for Olympic Games
TEAM 08

Students: Shivam Gupta (SXG190040), Shrey Shah(SXS190184), Seyyed Mohammadsaleh Hosseini (SXH175430), Wasif Haque(WAH180000) & Suvansh Kumar(SXK170058)

1. The Problem (5 points): Generate a search engine for Olympic Games

The goal of the project was to develop a simple search engine to show olympic games related information. To that end, we crawled the web to build an index of nearly 102920 web pages related to the Olympics, clustered the webpage contents and applied PageRank and HITS algorithms to get relevant results, carried out different types of query expansion techniques and observed their effects on relevance.

Following is overview of the entire project

One challenge we faced was using Scrapy for web crawling which turned out to be very time consuming and was not yielding good results. So resolved by moving over to Apache Nutz for crawling and indexing which made the whole process smoother.

Another challenge was that, initially we were using clustering to first cluster the results based by assigning a cluster for a given query. This approach seemed infeasible as it was not giving us good results. We instead opted to use Solr's search results using PageRank and HITS score and then refined them further using clustering to get better results.

Shivam Gupta(sxg190040)

2. Crawling (45 points):

In the beginning, We started crawling from the scrapy library of python with the implementation of the Breadth first traversal(BFS) and it was giving good results, we were able to crawl around 1 million web pages, but there were certain issues with scrapy like it was giving us multiple duplicate links and it was giving certain irrelevant links. Another issue with scrapy was that it was quite difficult to integrate this crawling with Indexing and relevance models. So We explored a lot and figured out a famous Crawler named as "Apache Nutch" which is coded entirely in the [JAVA programming language](#) and is so fast So we gathered around 76 URLs relevant to the Olympics from official websites to sports channels from different sources. **Seed links** are the initial source from where the URLs are going to crawl as the beginning point and create a web graph. We used about 76 seed links (Web links) in our Crawling process mentioned as follows:

'<https://www.olympic.org>'

We also handled the RLs(similar content but URL) are optionally marked in the CrawlDb and are the deleted afterwards during the process of in the indexing via Apache Solr, So we removes the duplicate URLs by following ways:

MapReduce "dedup":

- **Map:** Identities hashmap(dictionary) where keys are digests and values are CrawlDatum records
- **Reduce:** CrawlDatums with the same digest are marked (except one of them) as duplicates. There are multiple heuristics available to choose from of the item which is not marked as duplicate - the one with the shortest URL, fetched most recently, or with the highest score.

So We extracted and installed Apache Nutch on csgrads1.utdallas.edu UTD Linux server and gave the JAVA path variables over there as the Nutch is completely written in java, so that was really important to run our crawler

Crawling in Apache Nutch was done into the following steps:

- **Injecting** seed URLs into Nutch crawl database. Nutch Crawl Database contains all the links that have been parsed or is to be parsed by Nutch.
- **Then generating segments** for the list of injected URLs. This step ensures whether the link given for crawling has already been parsed or not and if it follows the regex of allowed URLs.
- Nutch then starts to crawl the links in the segment .In this step Nutch parses the webpage to look for the contents as well as any outgoing URLs in the page.

4) After Nutch has crawled a set of URLs those URLs are merged with the crawl database. For each URL parse Nutch makes an entry to the link database of the URLs a particular URL is referring to.

We did the crawling in segmentation to make sure that if any error occurs in the middle we need not to start the crawling process from the starting seed links. We initially injected 76 seed links in Nutch. We took segments of 1000 URLs to be crawled at a time to ensure better crawled data.

Apache Nutch crawling data contains 3 folder:

- 1) **CrawlDb** - It contains all the URLs which are parsed by the Nutch.

2) **LinkDB** - It contains for every URL(link) outgoing and the incoming URLs.

3) **Segment** - It contains the list of URLs to be crawled or being crawled. In order to pass hyperlink information, I gave read permissions to all of the data which we collected and explained the crawled output of Nutch in order to provide Apache Solr for the creation of the indexes so that they would be

able to read the *data efficiently* and create the indexes. Nutch commands which we used to crawl on UTD Linux server (First loading the top 1000 Links, then declaring a variable(\$s2) to put the crawled segment into a variable, then fetching the links and the contents, then parsing those data to \$s2 and updating the Database with the crawled data)

```
bin/nutch generate crawl/crawldb crawl/segments -topN 1000
```

First loading the top 1000 Links

```
s2=`ls -d crawl/segments/2* | tail -1`x
```

declaring a variable(\$s2) to put the crawled segment into a variable

```
bin/nutch fetch $s2
```

fetching the links and the contents

```
bin/nutch parse $s2
```

then parsing those data to \$s2

```
bin/nutch updatedb crawl/crawldb $s2
```

```
## and updating the Database with the crawled data
```

```
/crawl -i -D Solr.server.URL=http://localhost:8983/Solr/ URLs/ TestCrawl/ 3
```

```
crawl [-i|--index] [D "key=value"] <Seed Dir> <Crawl Dir> <Num Rounds>
```

-i|--index Indexes crawl results into a configured indexer

-D A Java property to pass to Nutch calls

Seed Directory Directory in which to look for a seeds file(in a text file(seed.txt))

Crawl Dir Directory where the crawl/link/segments dirs are saved

Num Rounds The number of rounds to run crawling for

We used Apache Solr to index documents crawled by Nutch .We used one of the Nutch commands mentioned above which crawls and directly sends the contents parsed from URL by Nutch to Solr for indexing. In order to allow Nutch to directly send its contents to Solr we have to change Solr's schema.xml for the collection we were using in Solr. We have directly supplied the crawled contents from Apache Nutch to Apache Solr for indexing purposes.

In the above command -i tells Nutch to send its parsed content to the assigned indexer which is Solr in our case.

To provide URLs for PageRank and HITS algorithm we generated a dump out of linkdb of Nutch.

We also implemented a Python program to read the above dump and generate for each URL parse a URL id and to create a graph from it using the networkx library from python.

Some screenshots during Crawling on CSGrad UTD Linux Server

```

We also created a webgraph which contains the information about Inlinks and Outlinks which helps in calculating the HITS (Hyperlink-Induced Topic Search)

Web graph information is as follows:

Total Number of links = 91441

Total Number of nodes = 25587

In the end, We generated like 102920 webpages. These files created via Apache were further used for Indexing and building Relevance model

3. Indexing and Relevance

Indexing

We have used Apache Solr for indexing the crawled pages. The following command has been used to create the index of crawled pages in Solr with the help of nutch:

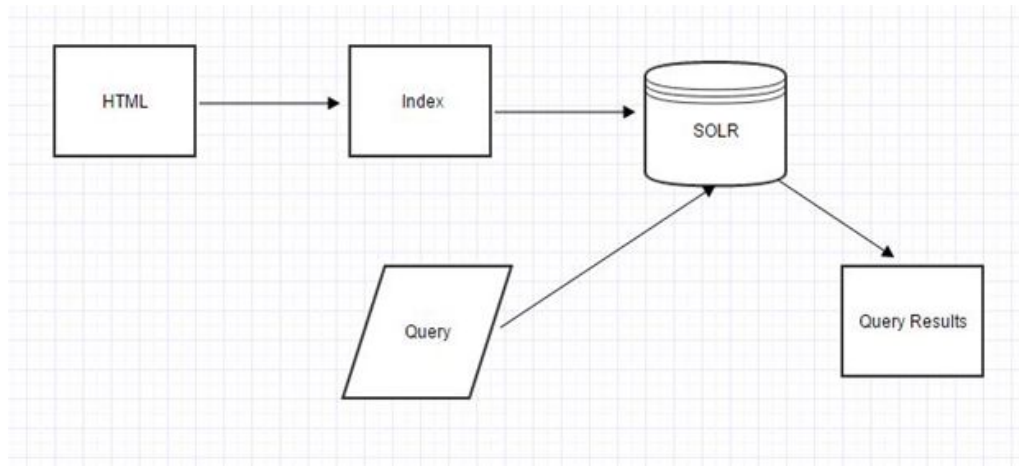

```
bin/nutch index crawl/crawlddb/ -linkdb crawl/linkdb -dir crawl/segments/ -filter -normalize -  
deleteGone
```

bin/nutch is the binary of Apache nutch. The index command takes the content crawlddb and passes it to IndexWriter plugins which has Solr set as the indexer.

Crawl data of nutch is made up of three components

- 1) **CrawlDb** - It contains all the link parsed by the Nutch.
- 2) **LinkDB** - It contains outgoing and the incoming URLs for each webpage.
- 3) **Segment** - It contains the list of URLs to be crawled or being crawled for incremental crawl.

Index Creation Flow Diagram

Webgraph and Statistics

We have used nutch command to create the webgraph of all the crawled webpages.

```
bin/nutch webgraph -segmentDir crawl/segments/ -webgraphdb crawl/webgraphdb
```

The webgraph command of nutch takes multiple segments to process and requires an output directory in which to place the completed web graph components. The webgraph creates three different components: an inlink database, an outlink database and a node database. The inlink database is a listing of url and all of its inlinks. The outlink database is a listing of url and all of its outlinks. The node database is a listing of url with node meta information including the number of inlinks and outlinks.

Statistics

Total Number of links = 91441

Total Number of nodes = 25587

The largest number of ingoing links = 5674

The largest number of outgoing links = 205

Web graph information connected to index

While creating index in Solr, we have run the LinkRank program of nutch to perform an iterative link analysis with the webgraph. LinkRank is a pagerank-like link analysis program that converges to stable global scores for each url. The LinkRank program starts with a common score for all urls. It then creates a global score for each url based on the number of incoming links and the scores for those links and the number of outgoing links from the page.

Relevance Models

Vector Space Relevance model

Solr provides tf-idf based relevance model to score the webpages and we made use of this model as vector space relevance model. In vector space relevance model, documents and queries are both vectors. Similarity of a document vector to a query vector can be computed by taking the cosine of the angle between them. Cosine similarity measure has been used to get the similarity between document and query. This scoring model depends on number of factors –

Term frequency - The frequency with which a term appears in a document. Given a search query,

the higher the term frequency, the higher the document score.

Inverse document frequency - The rarer a term is across all documents in the index, the higher its contribution to the score.

Tf-idf weighting scheme has been used to create the relevance model. In this weighting scheme,

$$W_{d,t} = \text{tf}_{d,t} \times \text{idf}_t$$

Tf-idf weighting scheme is the most common weighting scheme in vector space relevance model.

Page Rank

To develop the relevance model based on Page Ranking, we used inbuilt nutch command. The damping factor used is 0.80. Following are the steps we followed in order to apply PageRank scores into crawled database so that query results will display web pages in the descending order of page ranking values –

1. Create a web graph from the set of URLs fetched by the crawler

```
bin/nutch webgraph -segmentDir crawl/segments/ -webgraphdb crawl/webgraphdb
```

2. Run PageRank algorithm iteratively until the score converges

```
bin/nutch linkrank -webgraphdb crawl/webgraphdb/
```

3. Update the page rank score into the crawled database

```
bin/nutch scoreupdater -crawldb crawl/crawldb - webgraphdb crawl/webgraphdb/
```

4. Finally, index the updated crawled database using Solr and nutch command:

```
bin/nutch index crawl/crawldb -linkdb crawl/linkdb -dir crawl/segments/
```

HITS (Hyperlink Induced Topic Search)

For the HITS score, we created our own python program to generate the authority and the hub score in python. HITS uses hubs and authorities to define a recursive relationship between webpages.

Given a query to a Search Engine, the set of highly relevant web pages are called **Roots**. They are potential **Authorities**. Pages which are not very relevant but point to pages in the Root are called **Hubs**. Thus, an Authority is a page that many hubs link to whereas a Hub is a page that links to many authorities.

We used the **networkx library** to create the graph through the inlinks and outlinks information of all the nodes (urls) and ran the hits algorithm on the graph to generate the hub and the authority scores. To get these inlinks, we used nutch and generated a dump of the all the inlinks of crawled pages. With the inlinks dictionary, we created the outlinks as well. Based on the query provided by the user, root set of web pages are collected based on page rank results. The root set is converted to a base set by adding out link and inlinks of the root set. After that, HIT score calculation is done by our python program and based on maximum authority score, relevant web pages are sorted and returned to the User Interface for display.

Among the webpages we crawled,

1. Highest hub score was assigned to <http://www.sports.cn/yjsy/index.html> ,score – 0.0356845
2. Highest authority score was assigned to: <http://www.sports.cn/yjsy/index.html> ,score – 0.0625465

Topic based page ranking

For the purpose of testing Topic based page ranking, we have chosen 2 topics among countries:

1. swimming gold medals
2. opening ceremony

The results for **swimming gold medals** are as follows from our search engine

```
"url":  
https://www.olympics.com.au/resources/articles/australian-olympic-team-statistics-trivia/  
  
"title": "Australian Olympic Team Stati... | Australian Olympic Committee",

Collaboration with UI and test relevance models results

In collaboration with the person responsible for UI and clustering, we tested 20 queries and observed that the results of the query gets better after applying HIT score and clustering.

.....
4. User interface and comparisons with Google and Bing (45 points): written

Seyyed MohammadSaleh Hosseini (sxh175430) – User Interface

The front end is rendered using HTML, CSS, and JQuery, and it is powered by PHP in the backend. Bootstrap CSS library is used to design the page layout.

The search functionality enables the user to query for Olympics. We have shown the result of the query in six different tabs on the same page: the first tab contains the documents retrieved by vector similarity and then arranged based on the page rank. The second tab contains the results after using three different query expansion methods. There are three navigation tabs under the Query Expansion tab, each for showing the expanded query and the search results using that expanded query. The third tab shows the search results when clustering is used, and the fourth tab has the results for vector space model. Finally, the Google and Bing results are shown in tabs 5 and 6, respectively.

Getting Google and Bing Results:

We used API calls to fetch Google and Bing search results. For Google, the setup was done using the following link:

<https://cse.google.com/cse/all>

, and the call is made using the following link:

[https://www.googleapis.com/customsearch/v1?key=\\${APIKey}&cx=\\${searchEngineID}&q=\\${query}](https://www.googleapis.com/customsearch/v1?key=${APIKey}&cx=${searchEngineID}&q=${query})

For Bing, the setup was done using the following link:

<https://docs.microsoft.com/en-us/azure/cognitive-services/bing-custom-search/quick-start>

Seyyed MohammadSaleh Hosseini (sxh175430) – User Interface

, and the call is made using the following link:

```
https://api.cognitive.microsoft.com/bing/v7.0/search?q={$query}&count={$count}&offset={$offset}&mkt={$mkt}&safesearch={$safesearch}
```

Since a GET request with the header “Ocp-Apim-Subscription-Key: {\$subscriptionKey}” must be sent to the Bing server, I used curl library in PHP to do so.

An API is written by Shrey which takes a request in the following format:

```
http://127.0.0.1:5000//api/v1/indexer?query={$query}&type={$type}
```

in which \$query is the query and \$type shows what type of answer is needed (for instance it can be “vector” to get the vector space model results or “clustering” to get the clustering results).

The following steps are performed when user searches for a query:

1. Read the query given by the user
2. Call Google API and BING API to fetch the results from Google and Bing, respectively
3. Send different requests to the API written by Shrey and get the results for page rank, query expansion, clustering, HITS, and vector space.
4. Render the json results into HTML
5. Display all the results in different tabs

More than 20 queries were tested to evaluate then. 10 queries were tested with collaboration with Shrey who was in charge of relevance models, and the rest were done on my own.

Clustering is done by Wasif. The results from clustering are fetched using the API that Shrey has written.

By comparing our results to Google and Bing, we can see that, in some cases, our methods are giving results that are related to Olympics, whereas Google and Bing do not do so. This happens, for instance, for the query “Usain Bolt” as it is also visible in the screenshots. However, in most of the cases, our methods have subjectively the same performance as Google and Bing. For instance, for the query

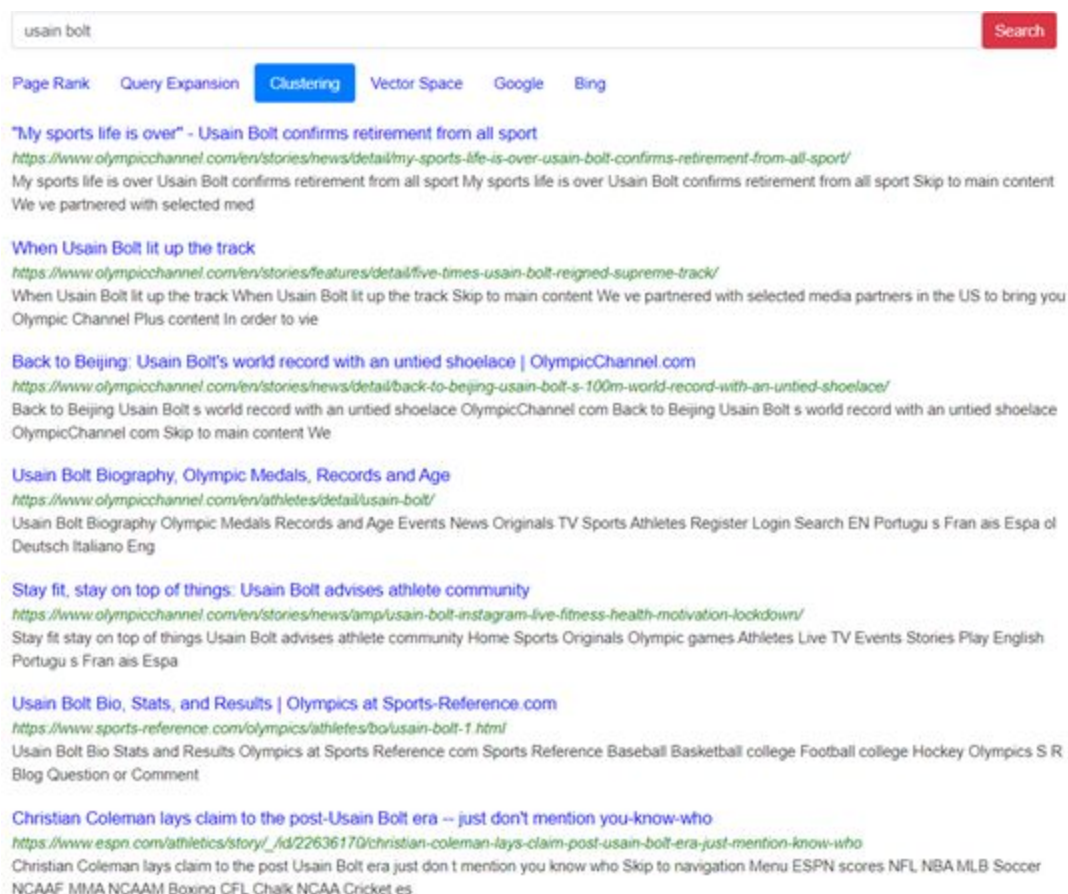

“Lionel Messi”, our methods do not show any results related to Olympics. This is probably a problem related to the crawler since we only crawled around 100,000 pages.

Seyyed MohammadSaleh Hosseini (sxh175430) – User Interface

As mentioned before, the clustering results are fetched using the API in a json file, and then, they are shown in “Clustering” tab.

We have decided to demonstrate the results for which our system is giving better results than Google and Bing as well as results for some queries for which our results are the same as Google and Bing.

Some screenshots of the system follow:

Wasif Haque (wah180000) - Clustering

5. Clustering (45 points):

Name: Wasif Haque, NetID: wah180000

Pre-processing

Before performing clustering, the content of the indexed documents needed to be cleaned and vectorized. From the index file (From Shrey Shah), I loaded all the document contents and ran them through some text processing such as removing punctuations, stopwords, expanding contractions, removing digits but keeping years etc. for all the 39232 documents that were indexed.

After that TfidfVectorizer from scikit-learn was used to convert the processed documents to a 1000 dimensional vector space. Tf-idf vectorization took into account top 1000 terms in order to prevent the vector size from being too large while capturing the most important terms for vectorization.

Clustering

Once the vectors were prepared, I used K-Means and Agglomerative clustering on those vectors to group related documents together using the scikit-learn library.

K-Means clustering

Given a set of d documents where each document is represented by an n dimensional vector in some vector space k -means clustering partitions the documents in k sets (or clusters) by minimizing the within-cluster sum of squares. Here is a list of steps that are carried out:

- First an initial set of k means are initialized.
- Assign each document to the cluster with the nearest (by least squared euclidean distance) mean
- Recalculate means (or centroids) for the observations assigned to each cluster.
- Repeat until convergence.

Agglomerative clustering

Agglomerative clustering is a type of hierarchical clustering technique approach: each observation starts in its own cluster, and pairs of clusters are merged as one moves up the hierarchy. So, for each documents are initially assigned to their own clusters and then they are continually merged to hierarchically generate new clusters based on the distances (in this implementation, ward distance is used - ward minimizes the variance of the clusters being merged) between them. I used the scikit-learn library to implement agglomerative clustering

Wasif Haque (wah180000) - Clustering

Effect on Relevance

Given a search query search results are fetched from solr and ranked using PageRank. The top 100 results from PageRank were then compared with the clusters to reshuffle the ranking of the page which improved relevance of the search results. Here are examples of some query results -

I tested around 20 queries to check the relevance output. The queries were chosen based on different olympic venues, olympic participants and winners. The results were judged by manual inspection.

6. Query expansion and relevance feedback (45 points):

Written by the student that worked on this module. Describe how you have selected 20 queries to test the Rocchio algorithm of your search engine - list them in your reports (3 points). Give examples of the web pages that you found relevant and those that you found irrelevant – and explain your judgements (3 points). Show also the modified queries that resulted by applying Rocchio to your original queries (3 points). Discuss the 50 queries that you have used for pseudo-relevance feedback (3 points). For each of the three methods, i.e. associative clustering, metric clustering and scalar clustering show (1) examples of 3 queries, the local document set (2 points x 3); (2) the local vocabulary and set of local stems as well as their vocabularies (2 points x 3); (3) show the values of the correlations you computed for the queries, and discuss your selection of the clusters (2 points x 3); and (4) show the resulting expanded queries (2 points x 3). Also show the results of the search engine on your expanded queries and discuss them (3 points). Elaborate on how you have collaborated with the student responsible for the user interface to expose the results of your expanded queries as well (3 points). Discuss which queries and their expansion you selected for the demonstration of the project (3 points). Make sure that the name of the student responsible for this module appears prominently, along with the student netID on every page of the description of the query expansion usage in your team's search engine (5 points will be deducted if name/netID are missing).

Response

Various local and global methods can be used to improve the search results. Following are some of the local methods that can be used for query expansion:

1. Relevance Feedback (Rocchio Algorithm)
2. Pseudo Relevance Feedback:
 - Association cluster
 - Metric cluster
 - Scalar cluster

The following formula is used to implement the Rocchio Algorithm:

$$\vec{q}_m = \alpha \vec{q}_0 + \beta \frac{1}{|D_r|} \sum_{\vec{d}_j \in D_r} \vec{d}_j - \gamma \frac{1}{|D_{nr}|} \sum_{\vec{d}_j \in D_{nr}} \vec{d}_j$$

20 queries were fed as q_0 as inputs. The algorithm was tested by setting certain values for the parameters ($\alpha=1.0$, $\beta=0.9$, $\gamma=0.1$).

Pseudo Relevance Feedback:

1. Association cluster: The stems which co-occur frequently inside documents have a synonymy association
2. Metric cluster: The stems which occur far apart in the document are less correlated to the terms that occur closer like in the same sentence.
3. Scalar cluster: The idea is that the two stems are more correlated if they have similar neighbourhoods.

20 queries chosen for testing Rocchio's algorithm:

1. 5 queries that have one keyword:
 - a. Gymnastics
 - b. Medals
 - c. Gold
 - d. Rio
 - e. Michael
2. 5 queries that are based on players:
 - a. Lionel Messi
 - b. Michael Phelps
 - c. Usain Bolt
 - d. Serena Williams
 - e. Dara Torres
3. 5 queries that were based on sports
 - a. Swimming
 - b. Soccer 2016
 - c. Tennis rio
 - d. marathon
 - e. London archery

4. 5 queries based on medalists

- a. Boxing medalists
- b. Top swimmers
- c. Marathon winner
- d. Tennis runner up
- e. Soccer champion

Query	Non Relevant Web Pages
tennis rio 2016	https://mobile.abc.net.au/news/rio-olympics-2016/sports/
Medals	https://en.wikipedia.org/wiki/Pierre_de_Coubertin_medal
	https://africa.espn.com/olympics/winter/2018/sports
	https://www.bbc.com/sport/olympics/37132833
gymnastics 2012	https://en.wikipedia.org/wiki/File:Synchronized_swimming_pictogram.svg
	https://en.wikipedia.org/wiki/File:Synchronized_swimming_pictogram.svg

We judge the first table results as relevant because the links answer the query that the user may have. When the user searches for medals, they would like to see the table showing who has won how many medals.

The results in the next table are marked as irrelevant because they do not reliably answer the questions of the user. When the query is related to gymnastics, the result of synchronized swimming pictogram is most probably not the best possible match that can be given.

Query	Modified Query
Gymnastics	Gymnastics beams
Medals	Medals olympics
gold	Gold bronze

Collaboration with student responsible for user interface:

- From the front-end user interface, the query is obtained in the form of a json request.
- The query is then searched on solr relevance model, then query is expanded and the new resulting documents are obtained.
- Finally, the expanded query, along with the resulting documents are collected, formed into a json response, and passed on to the user interface for displaying the results to the user.
- Collaboration was required with the student responsible for the user interface of our search engine, as the formats of request and response objects had to be decided and adjusted as our understanding of the project improved with time.
- A lot of issues crept in and needed to be accounted for. Changes had to be made to the back-end server programming to adjust to the requirements of the user interface.
- Special terms were added in the response from the server for query expansion, to ensure the results could be displayed correctly.

Discuss which queries and their expansion you selected for the demonstration of the project

I have chosen the following queries and their expansions:

Query	Expansion
Lionel Messi	Lionel Messi Ronaldo Cristiano Barcelona
Michael Phelps	Michael phelps medal
Tennis Rio	tennis rio 2016

.....
Suvansh Kumar (sxk170058), Shivam Gupta(sxg190040), Shrey Shah(sxs190184), Seyyed Mohammadsaleh Hosseini (SXH175430), Wasif Haque(WAH180000)

7. Discussion – all team.

The team discussed every part of the project at regular intervals on Microsoft teams to make sure everyone was on the same page regarding the technologies to use and the nexts tasks to be done by each team members. Also we conducted individual calls whenever necessary to integrate subcomponents or help each other in their respective parts. We used github for code versioning so that everyone could push code in a central repository and thus everyone had the access to the latest code without any hassle.

Also we used the linux servers provided by UTD to compute memory intensive tasks and due to that many components like crawling were run on different machines and the results were combined. This made it a lot more efficient to work rather than being stuck on some task due to its intensive nature.

.....
Suvansh Kumar (sxk170058), Shivam Gupta(sxg190040), Shrey Shah(sxs190184) Seyyed Mohammadsaleh Hosseini (SXH175430), Wasif Haque(WAH180000)

8. Conclusion – all team. (2.5 points will be deducted if name/netID are missing)

So in the end we would like to conclude that we have created this search engine specifically based on the Olympics. Like if a user wants to search for a specific olympics sports or medalists winners, our search engine is displaying the results according to the searched query. So in our search engine we crawled the data via Apache Nutch from specific seed links which are related to the olympics only, then we created the indexing based on the Crawled data from Apache Solr. We could manage to crawl only 100000 web pages so the results are not that good which are supposed to be in order to improve the search query we could crawl for 1 billion web pages. The clustering is also performed to improve the

results from our relevance model. The Page ranking is also performed in order to display the top results at the top so that the users don't need to scroll much in order to search for the results. The UI which we have created is pretty simple it is displaying the Title, URL and the small content of the webpage, this could be enhanced to images and videos as well just like Google but we need trillions of web pages to crawl and the indexing and the clustering files will also be so huge, So our search engine was giving pretty good and similar results with many of the Olympic medalists searches on our Search Engine like Michael Phelps and Carl Lewis who are the greatest olympics athletes of all time.
